

Application

Solenoid valves for controlling pneumatic actuators in hazardous areas

The Type 3963 Solenoid Valve provides a high level of operating safety and short actuating times for controlling pneumatic actuators in hazardous areas. Intrinsically safe, low-power binary signals issued by automation equipment or fieldbus systems can be used for controlling purposes.

Different switching functions, flow rates and connection types allow the variable configuration of the solenoid valve to suit individual applications (Fig. 1 to Fig. 3).

Design and principle of operation

Solenoid valves actuated on one side

The solenoid valves consist of an electropneumatic binary converter (A) with manual override (B, optional) and a booster valve (C) actuated on one side with return spring (Fig. 4).

The air supply for the electropneumatic binary converter (A) is routed internally through the booster valve (C) (delivered state). The solenoid valve can be converted to accept an external pilot supply at port 9 by turning a gasket.

The pressure reducer (5) reduces the supply air pressure to 1.4 bar.

In the idle position, the flapper (2) is lifted off the outlet nozzle (1) by the spring (3). As a result, a pressure lower than the deactivation pressure of the booster valve (C) builds up in the pressure divider, which consists of the restrictor (6) and outlet nozzle (1).

When the solenoid coil (4) is energized by an electric binary signal, the outlet nozzle (1) is closed by the flapper (2) against the force of the spring (3). This causes the pressure in the pressure divider to rise above the activation pressure of the booster valve (C), switching it to the operating position.

After the solenoid coil is de-energized, the booster valve (C) is switched to the neutral position again by a return spring.

Solenoid valves actuated on both sides

The solenoid valves consist of two electropneumatic binary converters (A) with manual override (B, optional) and a booster valve (C) actuated on both sides with two detent positions or spring-centered mid-position.

The air supply for the electropneumatic binary converters (A) is routed internally through the booster valve (C) (delivered state). The solenoid valve can be converted to accept an external pilot supply at port 9 by turning two gaskets.

The pressure reducer (5) reduces the supply air pressure to 1.4 bar.

In the idle position, the flapper (2) is lifted off the outlet nozzle (1) by the spring (3). As a result, a pressure lower than the deactivation pressure of the booster valve (C) builds up in the pressure divider, which consists of the restrictor (6) and outlet nozzle (1).

When the solenoid coil (4) is energized by an electric binary signal, the outlet nozzle (1) is closed by the flapper (2) against the force of the spring (3). This causes the pressure in the pressure divider to rise above the activation pressure of the booster valve (C), switching it to the operating position.

After the solenoid coil is de-energized, the operating position of the detented booster valve (C) is kept until the opposing signal is received. The spring-centered booster valve (C) is switched to the mid-position by a return spring after the solenoid coil is de-energized.

A simultaneous control of the electropneumatic binary converter (A) must be ruled out on the electric control level.
